A Garden Is More Than Plants

When we imagine a garden, we usually think about plants first. But a garden is a small ecosystem made up of much more than greenery.

Soil, insects, birds, water, sunlight, microorganisms, and plants constantly interact with one another. Even something as simple as a flowering plant can become a source of food for pollinators.

This makes biodiversity an important part of landscape design.

Using a variety of plants with different heights, textures, flowering periods, and functions can create more opportunities for different species to inhabit a space. Native and locally adapted plants can also play an important role in supporting the surrounding ecosystem.

A landscape does not have to be a perfectly controlled garden.

Sometimes, allowing a little wildness into a space can make it more alive.
